

ON THE RATE OF CONVERGENCE IN THE MULTIVARIATE CLT

By F. GÖTZE

University of Bielefeld

Berry–Esseen theorems are proved in the multidimensional central limit theorem without using Fourier methods. An effective and simple estimate of the error in the CLT for sums and convex sets using Stein's method and induction is derived. Furthermore, the error in the CLT for multivariate functions of independent random elements is estimated extending results of van Zwet and Friedrich to the multivariate case.

1. Introduction and results.

A. *The Berry–Esseen theorem for sums of independent random vectors.* Let X_1, X_2, \dots, X_n denote independent random vectors in \mathbb{R}^k . Let $\|\cdot\|$ denote the Euclidean norm in \mathbb{R}^k and define $S_n \triangleq X_1 + \dots + X_n$. Assume that

$$(1.1) \quad \beta_3 \triangleq \sum_{j=1}^n E\|X_j\|^3 < \infty.$$

For reasons of simplicity consider normed random vectors such that

$$(1.2) \quad EX_j = 0, j = 1, \dots, n \quad \text{and} \quad \text{Cov}(S_n) = k \times k\text{-identity}.$$

Let Φ denote the standard Gaussian distribution in \mathbb{R}^k and let $Q_{(n)}$ denote the distribution of S_n .

For indicator functions of measurable convex sets in \mathbb{R}^k , say f , and i.i.d. vectors X_j , the estimate $|\int f d(Q_{(n)}) - \Phi| \leq c(k)\beta_3$ has been proved by Sazonov (1968) using the so-called method of compositions due to Lindeberg (1922) and Bergström (1944). Using truncation techniques and more elaborate Fourier methods, Bhattacharya (1975) obtained this estimate uniformly over more general translation classes of (unbounded) functions f . Using a Fourier related approach, Sweeting (1977) provided estimates for individual functions f extending these results. The dependence of $c(k)$ on k for convex sets has been shown to be of order $O(k)$ by Nagaev (1976) which has been improved to $O(k^{1/2})$ by Bentkus (1986) for the i.i.d. case. First, we will provide a short inductive proof of the Berry–Esseen theorem in \mathbb{R}^k with explicit constant $c(k)$ for a class of functions including indicators of convex sets by the method of Stein (1972, 1987) adapted for \mathbb{R}^k in order to demonstrate the method.

Let \mathcal{A} denote a class of measurable functions uniformly bounded by some $K > 0$. For $f \in \mathcal{A}$ and $\delta > 0$, define $f_\delta^+(x) \triangleq \sup\{f(x+y) : \|y\| \leq \delta\}$ and

Key words and phrases. Central limit theorem, Berry–Esseen theorem, Stein's method, multivariate statistics.

$f_\delta^-(x) \triangleq -(-f)_\delta^+(x)$ and $\omega(f; \delta) \triangleq \int (f_\delta^+ - f_\delta^-) d\Phi$ as the average local variation of f . Furthermore, let $\|f\|_0 \triangleq \sup\{|f(x) - f(0)|: x \in \mathbb{R}^k\}$. We shall prove:

THEOREM 1.3. *Let \mathcal{A} be closed under the supremum and affine transformations, that is, $f \in \mathcal{A}$ implies $f_\delta^{+/-}$ and $x \mapsto f(Mx)$ are again in \mathcal{A} for every $\delta > 0$ and affine transformation M of \mathbb{R}^k . Assume that (1.1) holds and*

$$(1.4) \quad \sup\{\omega(f; \varepsilon): f \in \mathcal{A}\} \leq \Delta \varepsilon$$

for every $\varepsilon > 0$ and some $\Delta > 0$ not depending on n . Then

$$\sup\left\{\left|\int f d(Q_{(n)} - \Phi)\right|: f \in \mathcal{A}\right\} \leq C_k \beta_3 \sup\{\|f\|_0: f \in \mathcal{A}\},$$

where $C_k \triangleq 62.2a_k\Delta + 10.7$ and a_k^2 denotes the 0.875 quantile of the χ^2 -distribution with k degrees of freedom, that is, $a_k = 2.04, 2.4, 2.69, 2.94$ for $k = 2, 3, 4, 5$ and $a_k \leq 1.27k^{1/2}$ for $k \geq 6$.

In particular we obtain for the class \mathcal{C} of all measurable convex sets in \mathbb{R}^k , using the bound $\Delta \leq 2k^{1/2}$ which follows from Corollary 32, page 24 of Bhattacharya and Ranga Rao (1986) (using Stirling's formula),

$$(1.5) \quad \sup_{C \in \mathcal{C}} |Q_{(n)}(C) - \Phi(C)| \leq C_k \beta_3 n^{-1/2},$$

where $C_k = 124.4a_k k^{1/2} + 10.7 < 157.85k + 10$ for $k \geq 6$, which shows that these bounds are still of limited use for small sample sizes.

In the proof of Theorem 1.3 we shall use a multidimensional version of Stein's idea of defining differential equations in \mathbb{R}^1 . In order to motivate the choice of our equation, let us sketch one way of obtaining an equation which is useful for convergence rate estimates.

Assume that T_n , $n \in \mathbb{N}$ denotes a sequence of \mathbb{R}^k -valued statistics of n random elements X_1, \dots, X_n with limit distribution π on \mathbb{R}^k . Furthermore, let $V_{t,x}$, $t \geq 0$, denote a continuous time Markov process starting in $x \in \mathbb{R}^k$ with stationary distribution π and infinitesimal generator A . For a bounded measurable function h , we have the following formal identity using the diffusion equation for V_t :

$$\begin{aligned} h(x) - \pi(h) &= Eh(V_{0,x}) - Eh(V_{\infty,x}) \\ &= - \int_0^\infty \frac{\partial}{\partial t} Eh(V_{t,x}) dt \\ (1.6) \quad &= (A\psi)(x), \end{aligned}$$

where $\psi(x) \triangleq - \int_0^\infty Eh(V_{t,x}) dt$.

For some generators A , the r.h.s. of $Eh(T_n) - \pi(h) = EA\psi(T_n)$ can in fact now be estimated by means of Taylor expansions and partial integration. This describes our view of Stein's method.

In our case we may choose $\pi = \Phi$ and $V_{t,x}$ as the Ornstein–Uhlenbeck process

$$dV_{t,x} = -\frac{1}{2}V_{t,x} dt + dw_t, \quad V_{0,x} = x,$$

where w_t denotes the standard Brownian motion in \mathbb{R}^k and obtain as infinitesimal generator $A\psi(x) = \Delta\psi(x) - \psi^{(1)}(x)x$. Here Δ denotes the Laplace operator and $\psi^{(j)}v_1 \cdots v_j$ denotes the j th derivative of ψ in the directions $\vartheta_1, \dots, \vartheta_j \in \mathbb{R}^k$.

Replacing w_t by a Poisson process and π by a Poisson distribution, one obtains the difference equations of Barbour (1988) who treated the multivariate Poisson case. The defining equation

$$(1.7) \quad \Delta\psi(x) - \psi^{(1)}(x)x = h(x) - \Phi(h)$$

has to be interpreted carefully.

It is valid only for points x , where $h(x)$ is locally Hölder continuous. Applying this equation we need to evaluate expressions of type $E(\Delta\psi(S_n + x) - \Delta\psi(S_n + x'))$ which is made easier by introducing a smoothed version of $h - \Phi(h)$, say $-\chi_t(\cdot|h)$, $t > 0$ small, which is adapted to the equation (1.7). Define for $1 \geq t \geq 0$,

$$(1.8) \quad \chi_t(x|h) \triangleq \int (h(y) - h(t^{1/2}y + (1-t)^{1/2}x)) \Phi(dy).$$

Notice that in terms of the Ornstein–Uhlenbeck process $V_{t,x}$, we may write $-\chi_t(x|h) = E(h(V_{s,x}) - h(V_{\infty,x}))$, where $1 - e^{-s} \triangleq t$, since $\mathcal{D}(V_{s,x}) = \mathcal{D}(xe^{-s/2} + (1 - e^{-s})^{1/2}w_1)$. Then $-\chi_0(\cdot|h) = h - \Phi(h)$ and $\chi_1(\cdot|h) \equiv 0$.

Assuming that

$$(1.9) \quad \chi_t(x|h) = O_x(|\log(1-t)|^{-\gamma}) \quad \text{holds for } t \uparrow 1 \text{ and some } \gamma > 1,$$

the functions

$$(1.10) \quad \psi_t(x) \triangleq \frac{1}{2} \int_t^1 \chi_s(x|h) \frac{ds}{1-s}$$

are well-defined solutions of

$$(1.11) \quad \Delta\psi_t(x) - \psi_t^{(1)}(x)x = -\chi_t(x|h)$$

for every $x \in \mathbb{R}^k$ and $0 < t \leq 1$ [cf. Lemma 2.1(i)].

Of course we have to estimate the error in replacing $h - \Phi(h)$ by $-\chi_t(\cdot|h)$ by an appropriate smoothing inequality (see Lemma 2.11).

The equation (1.11) leads us to estimate

$$|Eh(S_n) - \Phi(h)| = |E\Delta\psi_t(S_n) - E\psi_t^{(1)}(S_n)S_n|$$

applying Stein's method similarly as in Bolthausen (1984) (in his proof of the Berry–Esseen theorem for general linear permutation statistics) combining the equation (1.11) with an induction on n .

Notice that in one dimension the connection with Stein's equation $f^{(1)}(x) - f(x)x = h(x) - \Phi(h)$ is given by $f(x) = \psi^{(1)}(x)$.

B. *A Berry–Esseen result for functions of independent random elements.* Let X_1, \dots, X_n denote independent random elements taking values in a measurable space $(\mathcal{X}, \mathcal{B})$. Let $t_n: \mathcal{X}^n \rightarrow \mathbb{R}^k$ denote a measurable function. We shall consider statistics of the type

$$T = t_n(X_1, \dots, X_n).$$

For convenience we may assume

$$(1.12) \quad ET = 0.$$

Define $T_j \triangleq E(T|X_j)$ and let $\lambda_j \triangleq$ [smallest eigenvalue of $\text{Cov}(T_1 + \dots + T_j)$]. Assume that (perhaps after rearrangement of X_1, \dots, X_n)

$$(1.13) \quad \text{Cov}(T_1 + \dots + T_n) = k \times k\text{-identity}, \quad \lambda_j \geq \frac{j}{2n}, \quad 1 \leq j \leq n.$$

Let $\Delta \triangleq T - \sum_{j=1}^n T_j$ denote the remainder in Hoeffding's projection. Define $\check{X}_j \triangleq (X_l: l \neq j)$ and assume that the following moments of first and second order differences measuring the stochastic influence of single observations and pairs of observations on Δ are well defined.

Let $\Delta_j \triangleq \Delta - E(\Delta|\check{X}_j)$, $\Delta_{jl} \triangleq \Delta_j - E(\Delta_j|\check{X}_l)$, $1 \leq j < l \leq n$ and define

$$(1.14) \quad \begin{aligned} \beta_3 &\triangleq \sum_{j=1}^n E\|T_j\|^3, & \beta_{3,0} &\triangleq \max_j E\|T_j\|^3, & \beta_{p,1} &\triangleq \max_{1 \leq j \leq n} E\|\Delta_j\|^p, \\ \beta_{p,2} &\triangleq \max_{1 \leq j < l \leq n} E\|\Delta_{jl}\|^p & \text{for } 2 \geq p \geq 1. \end{aligned}$$

THEOREM 1.15. *Assume that conditions (1.12)–(1.14) hold. Let f denote a measurable function such that $|f|_0 = \sup_x |f(x) - f(0)| < \infty$ and let S denote a random vector with standard normal distribution Φ . When $\frac{3}{2} \leq p < 2$, there exists a constant c depending on k and p only such that*

$$(1.16) \quad |Ef(T) - Ef(S)| \leq c|f|_0 \left(\beta_3 + \frac{1}{2-p} n^{3/2} \beta_{3,0}^{1/3} \beta_{p,1} + n^2 \beta_{3,0}^{2/3} \beta_{3/2,2}^{2/3} \right) + c\omega(f; c_1 \beta_3),$$

provided that $\beta_3 < c_2(\log n)^{-3}/k$, where c_1 and c_2 denote absolute constants.

The estimate extends results of van Zwet (1984) and Friedrich (1989) to the case of multivariate statistics T . Using a similar martingale decomposition for Δ as in the latter paper while avoiding Fourier inversion techniques, we arrive at a comparable error bound.

The proof is based on Theorem A.3 of the Appendix which might be of independent interest. This result can be also proved via Stein's method and the equation (1.6) and induction but for vectors T_j with nearly the same covariance and third moment behavior. Therefore we decided to give the shorter proof based on standard techniques.

A Berry–Esseen type estimate can be proved by the Stein method of Theorem 1.3 for multivariate functions of dependent random vectors like general rank and sampling statistics. The estimates depend on slightly higher moments of Δ_j as in (1.11) but not on moments of Δ_{ij} . Details will appear somewhere else.

REMARKS 1.17. (a) The estimate (1.16) remains true for $p = 2$ with $1/(2 - p)$ replaced by $\log n$.

(b) We have $\beta_{p,1} \leq n\beta_{p,2}$ [see (2.26)] and $\beta_{p,2}^{1/p} \geq \beta_{q,2}^{1/q}$, $p \geq q \geq 1$.

(c) Therefore, to achieve an error bound of order $O(n^{-1/2} + \omega(f; n^{-1/2}))$ in (1.16), we may assume $\beta_{3,0} = O(n^{-3/2})$ which implies $\beta_3 = O(n^{-1/2})$, together with

$$(1.18) \quad \beta_{3/2,2}^{2/3} = O(n^{-3/2})$$

and

$$(1.19) \quad \beta_{p,1} = O(n^{-3/2}) \quad \text{or} \quad \beta_{p,2} = O(n^{-5/2}) \quad \text{for } \frac{3}{2} \leq p < 2.$$

The assumptions (1.18) and (1.19) follow from

$$(1.20) \quad \beta_{5/3,2}^{3/5} = O(n^{-3/2}).$$

(d) In the case of a U -statistic $U \triangleq \sum_{i \leq i_1 < \dots < i_r \leq n} h_{i_1, \dots, i_r}$, where $h_{i_1, \dots, i_r} \triangleq h_{i_1, \dots, i_r}(X_{i_1}, \dots, X_{i_r})$ and $h_{i_1, \dots, i_r}(\cdot)$ denotes a measurable function of \mathcal{X}^r to \mathbb{R} , it follows by Minkowsky's inequality that (1.20) holds provided that

$$(1.21) \quad \max_{1 \leq j_1 < \dots < j_r \leq n} \left(E \|h_{j_1, \dots, j_r}\|^{5/3} \right)^{3/5} \leq Dn^{-r+1/2}, \quad D > 0.$$

For further applications to L - and R -statistics, see Friederich (1988) and van Zwet (1984).

These moment conditions sharpen results on the error in the CLT for multivariate U -statistics of degree two by Götze (1987) which were obtained by using characteristic function methods.

2. Lemmas and proofs of the results. For a measure Q on \mathbb{R}^k and $\varepsilon > 0$, define $Q_\varepsilon(A) \triangleq Q(\varepsilon^{-1}A)$. Let h denote a bounded measurable function.

LEMMA 2.1. (i) For every $x \in \mathbb{R}^k$, $0 < t \leq 1$, we have

$$(2.2) \quad \Delta\psi_t(x) - \psi_t^{(1)}(x)x = -\chi_t(x|h).$$

(ii) There exist absolute constants $c_j > 0$ such that for $t > 0$,

$$(2.3) \quad \sup_x |\psi_t^{(j)}(x)| \leq c_j |h|_0 A_j(t),$$

where $A_j(t) \triangleq t^{-(j-2)/2}$, $j > 2$, $A_2(t) \triangleq \log(t^{-1})$ and $A_1(t) \triangleq A_0(t) \triangleq 1$. For $k = 1$, we have $A_2(t) \triangleq 1$.

(iii) Let Q denote a finite (signed) Borel measure on \mathbb{R}^k . Then

$$(2.4) \quad \left| \int \psi_t^{(j)}(x) v^j Q(dx) \right| \leq c_j A_j(t) \sup \left\{ \left| \int h(xs + a) Q(dx) \right| : 0 \leq s \leq 1, a \in \mathbb{R}^k \right\} \|v\|^j$$

for every $1 > t > 0$ and $j \geq 1$. Note for later use that we may choose $c_3 \triangleq (1-t)^{1/2} \alpha_3$, with $\alpha_3 \triangleq \int |\varphi^{(3)}(y) v^3| d^k y \leq 1.602 \|v\|^3$.

PROOF. (i) In order to validate the formal calculations of (1.6), notice that by change of variables $y \rightarrow t^{-1/2}(y - (1-t)^{1/2}x)$,

$$(2.5) \quad \chi_t(x|h) = \int h d\Phi - \int h(y) \varphi_t(y - (1-t)^{1/2}x) d^k y,$$

where $\varphi_t(z) \triangleq t^{-k/2} \varphi(t^{-1/2}z)$ and $\varphi(z)$ denotes the Lebesgue density of the k -variate standard normal distribution Φ .

Now it is straightforward to verify that the equation

$$(2.6) \quad 2(1-t) \frac{d}{dt} u_t(x) = \Delta u_t(x) - u_t^{(1)}(x)x, \quad t > 0,$$

is satisfied for the functions $u_t(x) \triangleq \varphi_t(y - (1-t)^{1/2}x)$ with y arbitrary, $u_t(x) \triangleq \Phi(h)$ and thus for $u_t(x) \triangleq \chi_t(x|h)$ by interchanging differentiations and integration in $y \in \mathbb{R}^k$. This is obviously allowed since h is uniformly bounded. Similar interchanges of differentiation and integration prove for $j \geq 1$,

$$(2.7) \quad \begin{aligned} |\chi_s^{(j)}(x|h) v^j| &\leq \sup \{ |h(y + x(1-s)^{1/2}) - h(0)| : y \in \mathbb{R}^k \} \\ &\times (1-s)^{j/2} \int |\varphi_s^{(j)}(y) v^j| d^k y \\ &\leq |h|_0 (1-s)^{j/2} s^{-j/2} \alpha_j \|v\|^j, \end{aligned}$$

where α_j denotes an absolute constant independent of k .

Now (2.6) implies, after division by $2(1-t)$ with $u_t(x) \triangleq -\chi_t(x|h)$ and $t > 0$,

$$(2.8) \quad \begin{aligned} \chi_1(x|h) - \chi_t(x|h) &= \int_t^1 ds \frac{d}{ds} \chi_s(x|h) \\ &= \frac{1}{2} \int_t^1 \Delta \chi_s(x|h) \frac{ds}{1-s} - \frac{1}{2} \int_t^1 \chi_s^{(1)}(x|h) x \frac{ds}{1-s}. \end{aligned}$$

Thus $\chi_1(x|h) \equiv 0$ and interchanging integration and differentiation in (2.8) which is justifiable because of (2.7) yields the result (2.2).

(ii) The estimates follow immediately from (2.7) by interchanging differentiation and integration in s . The estimates for $k = 1$ and $A_2(t)$ follow from the

properties of the function $\psi_t^{(1)}$ being a solution of Stein's equation [see Stein (1972)].

(iii) We have by Fubini's theorem and interchanging differentiation and integration,

$$\begin{aligned} \left| \int \psi_t^{(j)}(x) v^j Q(dx) \right| &= \left| \int_t^1 ds (1-s)^{-1+j/2} \right. \\ &\quad \times \left. \int h(y) \varphi_s^{(j)}(y - (1-s)^{1/2} x) v^j d^k y Q(dx) \right| \\ &= \left| \int_t^1 ds (1-s)^{-1+j/2} \right. \\ &\quad \times \left. \left(\int h(y - (1-s)^{1/2} x) Q(dx) \right) \varphi_s^{(j)}(y) v^j d^k y \right|, \end{aligned}$$

which yields the desired estimate (2.4) using the second step of (2.7). The value of c_3 follows by inspection of these arguments using $\frac{1}{2} \int_t^1 ds (1-s)^{1/2} s^{-3/2} \leq (1-t)^{1/2}$ and the fact that $\langle u, v \rangle$ has standard normal distribution under $\Phi(du)$ when $\|v\| = 1$. \square

LEMMA 2.9 (Stein's method). *Let \bar{X}_j denote an independent copy of X_j , $1 \leq j \leq n$. Furthermore, define $S_{n,j} \triangleq N_j(S_n - X_j)$, where N_j denotes a positive definite matrix such that $\text{Cov}(S_{n,j}) = k \times k$ -identity. Let τ be uniformly distributed in $[0, 1]$ and independent of X_1, \dots, X_n . Finally, let*

$$H_{j,t}(x|u, v) \triangleq E\psi_t^{(3)}(N_j^{-1}x + rv) \left(\frac{1}{3}(u+v)^3 - \left(\frac{4}{3} - \tau \right) v^3 - \frac{1}{3} u^3 \right).$$

Then

$$(2.10) \quad |E\chi_t(S_n|h)| = \left| \sum_{j=1}^n H_{j,t}(S_{n,j}|\bar{X}_j, X_j) \right|.$$

PROOF. Using (2.2), we have

$$\begin{aligned} -E\chi_t(S_n|h) &= E(\Delta\psi_t(S_n) - \psi_t^{(1)}(S_n)S_n) \\ &= \sum_{j=1}^n E(\psi_t^{(2)}(S_n)\bar{X}_j^2 - \psi_t^{(1)}(S_n)X_j) \\ &= \sum_{j=1}^n \left[E\psi_t^{(2)}(S_n - X_j)\bar{X}_j^2 + E\psi_t^{(3)}(S_n - (1-\tau)X_j)\bar{X}_j^2 X_j \right. \\ &\quad \left. - E\psi_t^{(1)}(S_n - X_j)X_j - E\psi_t^{(2)}(S_n - X_j)X_j^2 \right. \\ &\quad \left. - E\psi_t^{(3)}(S_n - (1-\tau)X_j)X_j^3(1-\tau) \right]. \end{aligned}$$

Since X_l and \bar{X}_j are independent for every l, j and \bar{X}_j and X_j have the same distribution, the first and fourth term in the square bracket cancel and the third term vanishes by independence of $S_n - X_j$ and X_j .

Since $\psi_t^{(3)}(\cdot)(u^2v - v^3(1 - \tau)) = \psi_t^{(3)}(\cdot)(\frac{1}{3}(u + v)^3 - (\frac{1}{3} + 1 - \tau)v^3 - \frac{1}{3}u^3)$, the second and fifth term together yield the function $H_{j,t}$. This proves (2.10). \square

LEMMA 2.11. Assume that (1.3) holds. For $\varepsilon > 0$, let $b \triangleq (1 - \varepsilon^2)$ and $\delta \triangleq \varepsilon/b$. Then

$$(2.12) \quad \sup \left\{ \left| \int f d(Q_{(n)} - \Phi) \right| : f \in A \right\} \\ \leq \frac{4}{3} \sup \left\{ \left| \int \chi_{\varepsilon^2}(\cdot|h) dQ_{(n)} \right| : h \in \mathcal{A} \right\} + \frac{5}{2} a_k \delta \Delta,$$

where a_k^2 is the $\frac{7}{8}$ -quantile of the χ^2 -distribution with k degrees of freedom.

PROOF. From standard smoothing inequalities [see Bhattacharya and Ranga Rao (1986), Lemma 11.14, page 95], we obtain the following upper bound for the l.h.s. of (2.12) using $\mathcal{A} = \{f(b^{-1}\cdot) : f \in \mathcal{A}\}$:

$$\left[\sup \left\{ \left| \int h d(Q_{(n)} - \Phi)_b * \Phi_\varepsilon \right| : h = f_{a\delta}^\pm(b^{-1}\cdot), f \in \mathcal{A} \right\} \right. \\ \left. + (\alpha + 1)a \delta \Delta \right] / (2\alpha - 1),$$

where $\alpha = \Phi(\|x\| \leq a_k) = \frac{7}{8}$ and $\Phi_\varepsilon(A)$ is defined at the start of Section 2. This together with $\int h d(Q_{(n)} - \Phi)_b * \Phi_\varepsilon = -\int \chi_{\varepsilon^2}(\cdot|h) dQ_{(n)}$ yields (2.12). \square

PROOF OF THEOREM 1.3. We shall show by induction on n that

$$(2.13) \quad \sup \left\{ \left| \int f d(Q_{(n)} - \Phi) \right| : f \in \mathcal{A} \right\} \leq C_k \beta_3,$$

$$\text{where } C_k = 62.2a_k \Delta + 10.7.$$

Notice that w.l.o.g. $\sup\{|f|_0 : f \in \mathcal{A}\} = 1$. Since $\beta_3 \geq n^{-1/2}\beta_2^{3/2} = n^{-1/2}k^{3/2}$ by Hölder's inequality, the estimate (2.10) obviously holds for $\beta_3 > C_k^{-1}$ or $n \leq n_0 \triangleq C_k^2 k^3$.

Assume that (2.13) has been proved for $n - 1 \geq n_0$. From Lemma 2.11, we conclude that it is sufficient to use (2.2) with $t = \varepsilon^2 > 0$ to be determined later. Notice that (1.9) holds since for $h \in \mathcal{A}$,

$$|\chi_t(x|h)| \leq \left| \int (h(y) - h(yt^{1/2} + (1-t)^{1/2}x)) I(\|y\| > (1-t)^{-1/2}) \Phi(dy) \right| \\ + \Phi(\|y\| > (1-t)^{1/2}) \\ \leq c\Delta((1-t)^{1/2}\|x\| + (1-t)^{1/2}) + O((1-t)^{k/2}), \quad k > 2, t \uparrow 1.$$

Let $Q_{n,j}$ denote the distribution of $S_{n,j}$. By Lemma 2.9, we may write

$$\begin{aligned}
 |E\chi_t(S_n|h)| &\leq \sum_{j=1}^n E \left| \int H_{j,\varepsilon^2}(\cdot|\bar{X}_j, X_j) dQ_{n,j} \right| \\
 &\leq \sum_{j=1}^n E \left| \int H_{j,\varepsilon^2}(\cdot|\bar{X}_j, X_j) d(Q_{n,j} - \Phi) \right| \\
 &\quad + \sum_{j=1}^n E \left| \int H_{j,\varepsilon^2}(\cdot|\bar{X}_j, X_j) d\Phi \right| \\
 &\triangleq I_1 + I_2, \quad \text{say.}
 \end{aligned}
 \tag{2.14}$$

Put $Q \triangleq Q_{n,j} - \Phi$ in Lemma 2.1(iii). Then (2.4) yields by the definition of H_{j,ε^2} ,

$$\begin{aligned}
 &\left| \int H_{j,\varepsilon^2}(x|\bar{X}_j, X_j)(Q_{n,j} - \Phi)(dx) \right| \\
 &\leq \alpha_3(1 - \varepsilon^2)^{1/2} \varepsilon^{-1} \sup \left\{ \left| \int f d(Q_{n,j} - \Phi) \right| : f \in \mathcal{A} \right\} \\
 &\quad \times \left(\frac{1}{3} \|\bar{X}_j + X_j\|^3 + \left(\frac{4}{3} - \tau\right) \|X_j\|^3 + \frac{1}{3} \|\bar{X}_j\|^3 \right).
 \end{aligned}
 \tag{2.15}$$

Hence we obtain by the induction hypothesis (2.13) taking expectations over \bar{X}_j , X_j and τ in (2.14) and using $\|\bar{X}_j + X_j\|^3 \leq 4(\|\bar{X}_j\|^3 + \|X_j\|^3)$ the inequality

$$\begin{aligned}
 I_1 &\leq \alpha_3(1 - \varepsilon^2) \varepsilon^{-1} \sum_{j=1}^n \left(\frac{4}{3} + \frac{4}{3} + \frac{4}{3} - E\tau + \frac{1}{3} \right) E \|X_j\|^3 C_k \\
 &\quad \times \sum_{\substack{1 \leq l \leq n \\ l \neq j}} E \|N_j X_l\|^3.
 \end{aligned}
 \tag{2.16}$$

Notice that in order to apply the induction hypothesis we have to use the fact that \mathcal{A} is invariant under $x \rightarrow N_j^{-1}x$.

Since $N_j^{-2} = \text{Cov}(S_n - X_j)$ and $\langle x, (Id - N_j^{-2})x \rangle = E \langle X_j, x \rangle^2 \leq \beta_3^{2/3} \|x\|^2$, the inequality $\beta_3 < C_k^{-1}$ implies $\|N_j x\| \leq f \|x\|$, where $f \leq (1 - C_k^{-2/3})^{1/2}$. Thus

$$I_1 \leq \beta_3 \left(\frac{23}{6} \alpha_3 f^3 (1 - \varepsilon^2)^{1/2} \varepsilon^{-1} \beta_3 C_k \right).
 \tag{2.17}$$

By (1.8), we obtain with $M_{j,t} \triangleq Id + (1 - t)(N_j^{-2} - Id)$,

$$\left| \int \chi_s(x + N_j^{-1}z) v^3 d\Phi(z) \right| = \int h d\Phi - \int h(y) \varphi_{M_{j,s}}(y - (1 - s)^{1/2}x) d^k y,$$

where φ_Σ denotes the k -variate normal density with covariance matrix Σ and

mean zero. Thus with α_3 defined in Lemma 2.1(iii),

$$\begin{aligned} \left| \int \psi_t^{(3)}(x + N_j^{-1}z) v^3 \Phi(dz) \right| &\leq \frac{1}{2} \int_t^1 ds (1-s)^{-1+3/2} \\ &\quad \times \left| \int h(y) \varphi_{M_{j,s}}^{(3)}(y - (1-s)^{1/2}x) v^3 d^k y \right| \\ &\leq \frac{1}{2} \frac{2}{3} |h|_0 \sup_s \int |\varphi_{M_{j,s}}^{(3)}(y) v^3| d^k y \\ &\leq \frac{1}{3} \sup_s \langle v M_{j,s}^{-1} v \rangle^{3/2} \alpha_3 \leq \frac{1}{3} f^3 \|v\|^3 \alpha_3. \end{aligned}$$

This inequality together with the definition of H_{j,ε^2} implies similarly as in (2.15)–(2.16),

$$(2.18) \quad I_2 \leq \frac{\alpha_3}{3} f^3 \sum_{j=1}^n \left(\frac{4}{3} + \frac{4}{3} + \frac{4}{3} - E\tau + \frac{1}{3} \right) E \|X_j\|^3 \leq \alpha_3 \beta_3 \frac{23}{18} f^3.$$

Hence (2.17)–(2.18) together with (2.14) and Lemma 2.11 yields

$$\begin{aligned} D &\triangleq \sup \left\{ \left| \int f d(Q_{(n)} - \Phi) \right| : f \in \mathcal{A} \right\} \\ &\leq \beta_3 \frac{23}{6} \alpha_3 f^3 \left((1 - \varepsilon^2)^{1/2} \varepsilon^{-1} \beta_3 C_k + \frac{1}{3} \right) + \frac{5}{2} a_k \varepsilon (1 - \varepsilon^2)^{-1/2} \Delta. \end{aligned}$$

Choosing ε optimally, that is, such that the first and third terms are approximately equal, we get $\varepsilon(1 - \varepsilon^2)^{-1/2} \triangleq (\frac{23}{15} C_k \alpha_3 f^3 / a_k \Delta)^{1/2} \beta_3$ and therefore

$$D \leq C_k \beta_3 \left[\frac{23}{18} \alpha_3 f^3 C_k^{-1} + C_k^{-1/2} 2 \left(\frac{115}{12} \alpha_3 a_k \Delta f^3 \right)^{1/2} \right].$$

Choosing C_k and hence n_0 sufficiently large, we obtain that the factor in square brackets is smaller than 1. More precisely: Since $C_k \beta_3 \leq 1$, we have $f \leq (1 - C_k^{-2/3})^{-1/2}$. Some tedious but straightforward numerical estimates now lead to the choice (2.10) for C_k thus completing the induction. \square

PROOF OF THEOREM 1.10. Let S and Y be random vectors independent of X_1, \dots, X_n with standard normal distribution and distribution K [defined in (A1)–(A2) of the Appendix] on \mathbb{R}^k . By the smoothing lemma of Sweeting (1977), Lemma 5, we have

$$\begin{aligned} D &\triangleq |Ef(T) - Ef(S)| \\ &\leq \frac{1}{2\alpha - 1} \left[\max_{+,-} |Ef_{b\varepsilon}^{\pm}(T + \varepsilon Y) - Ef_{b\varepsilon}^{\pm}(S + \varepsilon Y)| \right. \\ &\quad \left. + 2|f|_0 \dot{P}(\|Y\| > bl) + e^1 \omega(f; 2b\varepsilon) \right. \\ &\quad \left. + 2|f|_0 \varepsilon^{n-(k-2)} \exp[(\varepsilon^{n-2}/2)] + 2|f|_0 \left(\frac{1-\alpha}{\alpha} \right)^l \right], \end{aligned}$$

where $\alpha \triangleq P(\|Y\| > b) > \frac{1}{2}$, $0 < \varepsilon < \varepsilon' < 1/b$, $l \in \mathbb{N}$ s.t. $\varepsilon'' \triangleq lb\varepsilon' < 1$. Choosing $\varepsilon \triangleq c\beta_3$, $\varepsilon' \triangleq \varepsilon^{1/2}$ and $l = \lceil \varepsilon^{-1/2}/b \rceil$, we obtain for β_3 sufficiently small,

$$(2.19) \quad D \leq c \max_{+, -} |Ef_{b\varepsilon}^{\pm}(T + \varepsilon Y) - Ef_{b,\varepsilon}^{\pm}(S + \varepsilon Y)| + c|f|_0\beta_3 + c\omega(f; c\beta_3).$$

Write $g(x)$ for $Ef_{b\varepsilon}^{\pm}(x + \varepsilon Y)$. Then we have

$$(2.20) \quad |E(g(T) - g(s))| \leq |E(g(S_n) - g(S))| + \sum_{j=1}^n |E(g(S_{j-1}) - g(S_j))| \triangleq I + J_1 + \cdots + J_n,$$

say, where

$$S_j \triangleq T_1 + \cdots + T_j + E(T|X_{j+1}, \dots, X_n); \quad S_0 = T, \quad S_n = T_1 + \cdots + T_n.$$

By interchanging integration and differentiation, Theorem A.3 immediately leads (with h replaced by g) to

$$|E\psi_0^{(j)}(S_n - X_j + x)v^j| \leq c|h|_0\|v\|^j,$$

which together with Lemma 2.9 implies

$$(2.21) \quad I \leq c\beta_3.$$

In order to estimate J_l write

$$(2.22) \quad J_l \leq |E(g(S_{l-1}) - g(S_l) - g'(S_l)\delta_l)| + |Eg'(S_l)\delta_l| \triangleq J_{l,1} + J_{l,2},$$

say, where $\delta_l \triangleq E(\Delta|X_l, \dots, X_n) - E(\Delta|X_{l+1}, \dots, X_n)$. From Theorem A.3, we obtain for $1 < p \leq 2$, $0 \leq t \leq 1$, $\|a\| \leq \lambda_l^{1/2}$,

$$(2.23) \quad E|E(g^{(2)}(S_l + ta)|X_{l+1}, \dots, X_n)a^2| \leq c\lambda_l^{-p/2}\|a\|^p$$

and therefore

$$(2.24) \quad \begin{aligned} & E|E(g'(S_l + ta) - g'(S_l)|X_{l+1}, \dots, X_n)a| \\ & \leq c\lambda_l^{-p/2}\|a\|^p + c\lambda_l^{-1/2}\|a\|I(\|a\| > \lambda_l^{1/2}) \\ & \leq c\lambda_l^{-p/2}\|a\|^p. \end{aligned}$$

By assumption (1.13), $\lambda_j \geq j/2n$ and therefore (2.24) implies for $p < 2$,

$$(2.25) \quad \begin{aligned} \sum_{l=1}^n J_{l,1} & \leq cn^{p/2} \sum_{l=1}^n l^{-p/2} E\|\delta_l\|^p \\ & \leq \frac{c}{2-p} n^1 \max_l E\|\Delta_l\|^p = \frac{c}{2-p} n\beta_{p,1}, \end{aligned}$$

since by Hölder's inequality $E\|\delta_l\|^p \leq E\|\Delta_l\|^p$.

For $p = 2$, the factor $1/(2-p)$ may be replaced by $\log n$.

Furthermore, define $\delta_{l|m} \triangleq E(\delta_l|X_l, X_{m+1}, \dots, X_n)$ and $\delta_{l,m} \triangleq \delta_{l|m-1} - \delta_{l|m}$. Let $\delta_m = 0$, $\delta_{l|m} = 0$ and $\delta_{l,m} = 0$ for $l = 1, \dots, n-1$, $m > n$.

By Lemma 1 of Chatterji (1969), the martingale structure of S_m and $\delta_{j|l}$ yields for $1 \leq p \leq 2$,

$$(2.26) \quad \begin{aligned} E|S_m - S_l|^p &\leq 2^{2-p} \sum_{i=m+1}^l E|\delta_i|^p, \quad 0 \leq m < l \leq n, \\ E|\delta_{j|l} - \delta_{j|m}|^p &\leq 2^{2-p} \sum_{i=m+1}^l E|\delta_{j,i}|^p, \quad 1 \leq j < l < m \leq n. \end{aligned}$$

Rewriting $J_{l,2}$ we have

$$(2.27) \quad \begin{aligned} J_{l,2} &\leq \sum_{j=1}^{\lfloor n/l \rfloor} |Eg'(S_{jl})\delta_{l|jl} - Eg'(S_{(j+1)l})\delta_{l|(j+1)l}| \\ &\leq \sum_{j=1}^{\lfloor n/l \rfloor} (J_{l,j,3} + J_{l,j,4}), \end{aligned}$$

say, where

$$\begin{aligned} J_{l,j,3} &\triangleq |E(g'(S_{jl}) - g'(S_{(j+1)l}))\delta_{l|jl}|, \\ J_{l,j,4} &\triangleq \left| Eg'(S_{(j+1)l}) \sum_{m=1}^l \delta_{l,jl+m} \right|. \end{aligned}$$

Since by construction,

$$J_{l,j,3} = |E[(g'(S_{jl}) - g'(S_{(j+1)l})) - (g'(S_{jl} - T_l) - g'(S_{(j+1)l} - T_l))]\delta_{l|jl}|,$$

we obtain by similar arguments as in (2.24) using Hölder's inequality and (1.13),

$$\begin{aligned} J_{l,j,3} &\leq c\lambda_{jl}^{-(p+1)/2} E\|\delta_{l|jl}\| \|T_l\| \left\| \sum_{m=1}^l \delta_{jl+m} \right\|^{p-1} \\ &\leq c(jl)^{(p+1)/2} n^{(p+1)/2} E^{1/q} \left(\left\| \sum_{m=1}^l \delta_{jl+m} \right\|^{(p-1)q} \|T_l\|^q \right) E^{1/p} \|\delta_{l|jl}\|^p, \end{aligned}$$

where $1/p + 1/q = 1$. By independence of δ_{jl+m} and T_l , $p = (p-1)q$, together with $E\|\delta_{l|jl}\|^p \leq E\|\delta_l\|^p \leq E\|\Delta_l\|^p$ (Hölder's inequality) and $E\|\sum_{m=1}^l \delta_{jl+m}\|^p \leq l \max_m E\|\delta_{jl+m}\|^p$ [see (2.26)], we conclude

$$\begin{aligned} J_{l,j,3} &\leq cn^{(p+1)/2} j^{(p+1)/2} l^{(p+1)/2+1/q} E^{1/q} \|T_l\|^q \max_m (E^{1/q} \|\delta_{jl+m}\|^p) (E^{1/p} \|\Delta_l\|^p) \\ &\leq cn^{(p+1)/2} j^{(p+1)/2} l^{(p+1)/2+1/q} \beta_3^{1/3} \beta_{p,1}^{1/p+1/q}, \end{aligned}$$

by Hölder's inequality. Since $\sum_{j: jl \leq n} j^{(p+1)/2} \leq c(n/l)^{1+(p+1)/2}$, we have

$$(2.28) \quad \begin{aligned} \sum_{l=1}^n \sum_{jl \leq n} J_{l,j,3} &\leq c \frac{n^{(p+1)/2}}{2-p} \left(\sum_{l=1}^n \left(\frac{n}{l} \right)^{1+(p+1)/2} l^{(p+1)/2+1-1/p} \beta_{3,0}^{1/3} \beta_{p,1} \right) \\ &\leq c \frac{n^{2-1/p}}{2-p} \beta_{3,0}^{1/3} \beta_{p,1} \end{aligned}$$

for $1 \leq p < 2$. For $p = 2$, the factor $1/(2-p)$ may be replaced by $\log n$. Furthermore, write

$$J_{l,j,4} \leq \sum_{m=1}^l \left| E \left[(g'(S_{(j+1)l}) - g'(S_{(j+1)l} - T_l)) \right. \right. \\ \left. \left. - (g'(S_{(j+1)l} - T_{jl+m}) - g'(S_{(j+1)l} - T_l - T_{jl+m})) \right] \delta_{l,jl+m} \right|.$$

By similar arguments as in (2.24), we obtain

$$J_{l,j,4} \leq c \sum_{m=1}^l (jl+m)^{-3/2} n^{3/2} E \|\delta_{l,jl+m}\| \|T_l\| \|T_{jl+m}\|.$$

Hence, by

$$E(\|\delta_{j,jl+m}\| \|T_{jl+m}\| \|T_l\|) \leq E^{2/3} \|\delta_{j,jl+m}\|^{3/2} \|T_{jl+m}\|^{3/2} E^{1/3} \|T_l\|^3$$

and independence of T_{jl+m} and $\delta_{l,jl+m}$, we have

$$(2.29) \quad \sum_{l=1}^n \sum_{jl \leq n} J_{l,j,4} \leq cn^{3/2} \sum_{l=1}^n \sum_{t=l+1}^n (t-1)^{-3/2} \beta_{3,0}^{2/3} \beta_{3/2,2}^{2/3} \leq cn^2 \beta_{3,0}^{2/3} \beta_{3/2,2}^{2/3}.$$

Summarizing, we obtain by (2.19), (2.20), (2.25), (2.28) and (2.29)

$$(2.30) \quad D \leq c(\beta_3 + \omega(f; c\beta_3) + n^{3/2} \beta_{3,0}^{1/3} \beta_{p,1}/(2-p) + n^2 \beta_{3,0}^{2/3} \beta_{3/2,2}^{2/3}),$$

using

$$n\beta_{p,1} \leq cn^{3/2} \beta_{p,1} \beta_{3,0}^{1/3}. \quad \square$$

APPENDIX

Let Y denote a random vector independent of X_1, \dots, X_n with distribution K in \mathbb{R}^k and characteristic function $\hat{K}(t)$ satisfying

$$(A.1) \quad \int \|x\|^p K(dx) < \infty \quad \text{for every } p \in \mathbb{N},$$

$$(A.2) \quad |\hat{K}(t)| = 0 \quad \text{for every } t \text{ such that } \|t\| > 1.$$

For an example, see Bhattacharyya and Ranga Rao [(1986), Theorem 10.1, page 85].

The following result is a useful tool for deriving asymptotic expansions in the CLT for multivariate functions of independent random elements [see Götze (1985)], in so far as it does not require truncation.

THEOREM A.3. Assume that X_1, \dots, X_n denote independent random vectors in \mathbb{R}^k such that

$$(A.4) \quad EX_j = 0, \quad 1 \leq j \leq n, \quad \beta_s \triangleq \sum_{j=1}^n E\|X_j\|^s < \infty, \quad s \geq 3,$$

and

$$(A.5) \quad \lambda_n \triangleq \text{minimal eigenvalue of } \text{Cov}(X_1 + \dots + X_n) > 0.$$

Let f denote a measurable function $f: \mathbb{R}^k \rightarrow \mathbb{R}$ and assume

$$(A.6) \quad \begin{aligned} M_s(f) &\triangleq \sup\{f(x)/(1 + \|x\|^s) : x \in \mathbb{R}^k\} < \infty, \\ \beta_s \lambda_n^{-s/2} &< (\log n)^{-s}/16k. \end{aligned}$$

Then there is an absolute constant c_1 such that with $\varepsilon \triangleq c_1 \beta_3/\lambda_n$,

$$F(x) \triangleq Ef(X_1 + \dots + X_n + \varepsilon Y + x)$$

satisfies

$$|F^{(r)}(x)a^r| \leq c(r, k) M_s(f)(1 + \|x\|^s)(1 + \beta_2^{s/2})(1 + \lambda_n^{-r/2})\|a\|^r$$

for every $x, a \in \mathbb{R}^k$, $r \in \mathbb{N} \cup \{0\}$.

PROOF. For $I \subset \{1, \dots, n\}$, let $R_I \triangleq \sum_{j \in I} X_j$ and $R_n \triangleq X_1 + \dots + X_n$. Let k_ε denote the Lebesgue density of $K_\varepsilon(A) \triangleq K(\varepsilon^{-1}A)$. Let C_n denote a positive definite matrix such that $C_n R_n$ has covariance equal to the $k \times k$ -identity matrix. Replacing $f(x)$ by $\tilde{f}(x) = f(C_n^{-1}x)$, ε by $\tilde{\varepsilon} \triangleq \varepsilon/\lambda_n^{1/2}$ and K_ε by $\tilde{K}_{\tilde{\varepsilon}}(A) \triangleq K_\varepsilon(C_n^{-1}A)$, we obtain $M_s(\tilde{f}) \leq M_s(f)(1 + \|C_n^{-1}\|^s)$ and $\tilde{K}_{\tilde{\varepsilon}}(t) = 0$ for $\varepsilon\|C_n\|\|t\| = \tilde{\varepsilon}\|t\| > 1$. Thus (A.1)–(A.2) hold for \tilde{K} as well. Let c denote in the following a generic constant depending on k only. Writing $F(x) = E\tilde{f}(C_n R_n + \varepsilon C_n Y + C_n x)$, we conclude that it is sufficient to prove (A.6) for the normalized quantities above. In order to simplify notations we shall write again f instead of \tilde{f} , R_n instead of $C_n R_n$, etc.

Define $E'_I f \triangleq Ef \prod_{j \in I} I(\|X_j\| \leq 1)$. Then

$$(A.7) \quad \begin{aligned} D &\triangleq \int Ef(R_n + y)k_\varepsilon^{(r)}(y)a^r \prod_j (I(\|X_j\| \leq 1) + I(\|X_j\| > 1)) d^k y \\ &= \sum_I EF_I(R_{I^c}) \prod_{j \in I^c} I(\|X_j\| > 1), \end{aligned}$$

where $F_I(z) \triangleq \int E'_I f(R_I + z + y)k_\varepsilon^{(r)}(y)a^r d^k y$. We have

$$(A.8) \quad \begin{aligned} |F_I(z)| &\leq cM_s(f)(1 + \|z\|^s) \sup\{(1 + \|z\|^{k+1+s})E'_I k_\varepsilon^{(r)}(R_I + z)a^r : z \in \mathbb{R}^k\} \\ &\leq cM_s(f)(1 + \|z\|^s) \max_{|\beta| \leq k+1} \int |D^\beta(E'_I \exp[itR_I]\hat{K}(t\varepsilon)(ta)^r)| d^k t \\ &\leq cM_s(f)(1 + \|z\|^s), \end{aligned}$$

by Lemma 11.6 and Corollary 14.4 of Bhattacharya and Ranga Rao (1986), provided that $\beta_s \leq (16k(\log n)^s)^{-1}$ and $|I| > n - \log n$, n sufficiently large.

Here we have used $\|\text{Cov } R_I - Id\| \leq \beta_s^{2/s}(\log n)^{1-2/s} < \frac{1}{8}$ for n sufficiently large. From (A.7) and (A.8), we obtain

$$(A.9) \quad D \leq cM_s(f) \sum_{l=0}^{\log n} \sum_{|I|=n-l} E \prod_{j \in I} I(\|X_j\| > 1) \left(1 + l^{s-1} \sum_{j \notin I} E \|X_j\|^s I(\|X_j\| > 1) \right) \\ + cM_s(f) \sum_{l > \log n} \varepsilon^{-r} \sum_{|I|=n-l} E'_I \left(1 + \left\| \sum_{j \in I} X_j \right\|^s \right) \prod_{j \notin I} E \|X_j\|^s.$$

The estimate of the second summand of (A.9) follows from $|f(k_\varepsilon^{(r)}(y))| d^k y = O(\varepsilon^{-r})$ and $E I(\|X_j\| > 1) \leq E \|X_j\|^s$. Since

$$\sum_{|I|=l} \sum_{j \in I} E \|X_j\|^s I(\|X_j\| > 1) \prod_{l \in I, l \neq j} E \|X_l\|^s = o(\beta_s^l) l!^{-1},$$

we obtain from (A.9),

$$(A.10) \quad D \leq cM_s(f) \left\{ 1 + \sum_{l=1}^{\log n} l^{s-1} \beta_s^l l!^{-1} + \left(\sum_{l > \log n} c \beta_s^l l!^{-1} \right) \varepsilon^{-r} \right\} \\ \leq cM_s(f),$$

by our assumption on the size of β_s .

For the estimation of the second part of (A.9), we have used $E'_I \|R_I\|^p \leq c_p$ for every p [see, e.g., Götze and Hipp (1978), Lemma 4.5, page 75]. \square

Acknowledgment. I would like to thank the referee for valuable suggestions which helped to improve the manuscript.
